What Is a Heating Curve?

Definition and Significance

A heating curve is a graphical representation showing how the temperature of a substance changes as heat is added over time. It illustrates the phases of matter—solid, liquid, and gas—and the energy required to transition between these phases.

1. **Solid phase:** Temperature increases with heat input until melting point.
2. **Melting point:** Temperature plateaus during phase change, despite continuous heat addition.
3. **Liquid phase:** Temperature rises again as heat continues to be added.
4. **Boiling point:** Temperature remains constant during vaporization.
5. **Gas phase:** Temperature increases once boiling completes.

Sample Heating Curve Worksheet 1 Answers

Example Problem 1: Calculating Heat During Temperature Increase

Question: How much heat is needed to raise the temperature of 200 g of water from 20°C to 80°C? The specific heat capacity of water is 4.18 J/g°C.

Answer: Use the formula:

$$Q = mc\Delta T$$

Where:

1. $m = 200 \text{ g}$
2. $c = 4.18 \text{ J/g}^\circ\text{C}$
3. $\Delta T = 80^\circ\text{C} - 20^\circ\text{C} = 60^\circ\text{C}$

Calculating:

$$Q = 200 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times 60^\circ\text{C} = 50,160 \text{ J}$$

Answer: Approximately 50,160 Joules of heat are needed.

Example Problem 2: Identifying Phase Change on the Heating Curve

Question: At what point does water begin to boil on the heating curve? What is the significance of the plateau at this temperature?

Answer: Water begins to boil at 100°C under standard atmospheric pressure. The plateau at this temperature indicates the phase change from liquid to vapor, where heat energy is used for vaporization rather than increasing temperature.

Example Problem 3: Calculating Heat During Phase Change

Question: How much heat is required to convert 150 g of water at 100°C to steam at the same temperature? The heat of vaporization of water is 2260 J/g.

Answer: Use the formula:

$$Q = m \times L_v$$

1. $m = 150 \text{ g}$
2. $L_v = 2260 \text{ J/g}$

Calculating:

$$Q = 150 \text{ g} \times 2260 \text{ J/g} = 339,000 \text{ J}$$

Answer: 339,000 Joules of heat are required for vaporization.

Understanding the Phases of a Heating Curve

Phase 1: Heating the Solid

In this initial stage, heat is added to the solid, raising its temperature until it reaches its melting point. The temperature increase is linear, and the heat added can be calculated using specific heat capacity.

Phase 2: Melting the Solid

The temperature remains constant during melting as the energy is used to break bonds between solid particles. This phase change is represented by a horizontal line on the heating curve.

Phase 3: Heating the Liquid

After melting, heat continues to increase the temperature of the liquid until it reaches boiling point.

Phase 4: Vaporization

During boiling, temperature remains constant as energy goes into converting liquid into vapor. The horizontal plateau indicates this phase change.

Phase 5: Heating the Gas

Finally, the gas's temperature increases as heat is added beyond the boiling point.

Understanding the Concept of Heating Curves

Definition and Basic Principles

A heating curve graphically represents the temperature change of a substance as it absorbs heat over time or as heat is added at a controlled rate. Typically, the curve plots temperature (Y-axis) against the amount of heat energy supplied (X-axis). As heat is introduced to a substance—be it water, metal, or any other material—the temperature rises until a phase change occurs, such as melting or vaporization, where the temperature remains constant despite continued heat input. The core principles governing heating curves include:

- Specific Heat Capacity: The amount of heat needed to raise the temperature of a unit mass of a substance by one degree Celsius.
- Phase Changes: Transitions between solid, liquid, and gas phases, each involving latent heat.
- Latent Heat: The energy absorbed or released during a phase change

without temperature change. Understanding these principles allows students to interpret the shape and features of heating curves accurately.

Typical Features of Heating Curves

A standard heating curve consists of several distinct segments: 1. Solid Heating Region: The temperature of the solid increases linearly with heat added. 2. Melting Plateau: Temperature remains constant during the phase change from solid to liquid; latent heat of fusion is absorbed. 3. Liquid Heating Region: The liquid's temperature rises as heat continues to be added. 4. Vaporization Plateau: During vaporization, temperature stays constant while latent heat of vaporization is absorbed. 5. Gas Heating Region: The temperature of the gas increases after vaporization. Each segment reflects different energy transfer dynamics, and understanding their interplay is essential for solving related worksheet problems.

Question: A 50 g block of ice at -10°C is heated until it becomes steam at 120°C . Given specific heat capacities: - Ice: $2.09 \text{ J/g}^{\circ}\text{C}$ - Water: $4.18 \text{ J/g}^{\circ}\text{C}$ - Steam: $2.00 \text{ J/g}^{\circ}\text{C}$ Latent heats: - Fusion (melting): 334 J/g - Vaporization: 2260 J/g Calculate the total heat energy required for this process. Answer: Step 1: Heating ice from -10°C to 0°C $Q_1 = \text{mass} \times \text{specific heat of ice} \times \text{temperature change}$ $Q_1 = 50 \text{ g} \times 2.09 \text{ J/g}^{\circ}\text{C} \times (0 - (-10))^{\circ}\text{C} = 50 \times 2.09 \times 10 = 1045 \text{ J}$ Step 2: Melting ice at 0°C to water $Q_2 = \text{mass} \times \text{latent heat of fusion}$ $Q_2 = 50 \text{ g} \times 334 \text{ J/g} = 16,700 \text{ J}$ Step 3: Heating water from 0°C to 100°C $Q_3 = 50 \text{ g} \times 4.18 \text{ J/g}^{\circ}\text{C} \times (100 - 0)^{\circ}\text{C} = 50 \times 4.18 \times 100 = 20,900 \text{ J}$ Step 4: Vaporizing water at 100°C to steam $Q_4 = 50 \text{ g} \times 2260 \text{ J/g} = 113,000 \text{ J}$ Step 5: Heating steam from 100°C to 120°C $Q_5 = 50 \text{ g} \times 2.00 \text{ J/g}^{\circ}\text{C} \times (120 - 100)^{\circ}\text{C} = 50 \times 2 \times 20 = 2000 \text{ J}$ Total heat energy: $Q_{\text{total}} = Q_1 + Q_2 + Q_3 + Q_4 + Q_5$ $Q_{\text{total}} = 1045 + 16,700 + 20,900 + 113,000 + 2000 = 153,645 \text{ J}$ This detailed approach exemplifies how worksheet answers reinforce understanding of energy transfer during phase changes and temperature increases.

Sample Question 2: Interpreting the Heating Curve Graph

Question: Given a heating curve graph showing temperature vs. heat supplied, identify the phases at points A, B, and C, where: - Point A: Temperature = 0°C - Point B: Temperature = 100°C - Point C: Temperature = 120°C Answer: - Point A (0°C): This point is at the end of the solid heating phase or at the melting point. If the curve shows a flat segment at 0°C , it's during the melting process where solid is transforming into liquid. If the temperature is just starting to rise, it's the solid phase approaching melting.

- Point B (100°C): This point corresponds to the boiling point of water. If the curve flattens at 100°C, the substance is undergoing vaporization—liquid to gas. - Point C (120°C): Post-vaporization, the substance is in the gaseous phase, and temperature increases beyond the boiling point, indicating superheated steam. Interpreting such graphs helps students correlate phases with temperature plateaus and rising segments, a key skill in understanding thermodynamic processes.
